# **Chapter 1: Algorithms and Flowcharts**

## Recap

Till now we have gone through an experiential learning around Artificial Intelligence in which we got to know about so many new concepts like what is Artificial Intelligence, Machine Learning, Deep learning, Rule-based approach, learning based approach, neural networks, etc. Now, it is time to move ahead in this journey towards AI Readiness and work around the concepts we are introduced to through hands-on learning sessions.

But before we start getting our hands dirty, let us recall what has been done so far. Here is a quiz through which you can challenge yourself and see how well do you remember things.

## Quiz Time!

1. Which stage is missing in AI Project Cycle?

2. Which one of the following is not an SDG?

Life Under Water	Home for All
No Poverty	Partnership for the Goals

For Techno India NJR Institute of Technology Pankaj KumarsPorw (Principal)

3. What will be the output for this program?

# options = ['data','AI', 'CV', 'NLP'] choice = 1 print(options[1])

4. Large Neural Networks are time consuming and computationally expensive.

TRUE FALSE
------------

5. Which one of the following is not an AI application?

Facial Recognition	Writing Suggestion in Gmail
Kahoot	Google Maps

6. What is this flowchart for?

Find Largest Number	Print X & Y
Take X & Y as Input	None of the Above

For Techno India NJR Institute of Technology परिवा Ur Pankaj Kumaro Porwa (Principal)

7. Google Deep Mind AI is based on reinforcement learning.

TRUE

FALSE

8. Wikipedia can be an appropriate Data Source for which domain?

Data Science	Computer Vision
Natural Language Processing	None of the Above

9. What is the correct step to reach finish from first?

10. Pixel It is an example of machine learning AI approach.

11. AI can be implemented in which of the following field?

Medical Science	Agriculture
Education	All of the above

12. Problem statement template does not talk about goal of the project?

	TRUE	FALSE
13.	Snapchat is an example of Natural La	anguage Processing domain?

TRUE	FALSE

14. Which of the following is commonly used for image processing in python?

Pandas	Matplotlib
OpenCV	For Techno Mole the Titzai or
	Dr. Pankaj Kumar-Pelwa (Principal)

15. Box plots help in finding out\_\_\_\_?

Erroneous Data	Outliers	
Mean of the data	None of the above	

16. The AI domain which can be used to predict the Air Quality Index is?

Data Science	Computer Vision	
Natural Language Processing	None of the Above	

## 17. Where is decision tree used?

Classification	Regression	
Clustering	Dimensionality Reduction	

## 18. Which process is depicted by these steps?

Calculate average marks	Calculate sum	
Calculate percentage	Analyse marks of student	

## 19. Which of the following is used to plot graphs in python?

Numpy	Pandas	
Scikit	Matplotlib	

20. How was the overall experience of the workshop?

It was great!	It was too complicated!	
lt was easy & understandable	It was boring	

How well did you score in the quiz? \_\_\_\_\_\_ Analyze your thoughts here:

For Techno India NJR Institute of Technology Tan J Tan and Dr. Pankaj KumargPorwa (Principal)

## Introduction

Every machine, whether AI enabled or not, follows a particular path of action. It goes through exact specific steps which have been programmed into it to accomplish the given task. For example, a washing machine can wash clothes for us and not do anything else because it is designed explicitly for this task. It follows the steps programmed into it and completes the work.

Can you think of possible steps to wash clothes in a washing machine?

Ever wondered how do people create such programs? Write your thoughts below. For Techno India NJR Institute of Technology

To develop a program, the very first step that comes into the picture is to specify the task which the machine needs to do. Once the task or the main objective of the program is finalized, the task is broken into smaller tasks which altogether contribute towards achieving the main goal. To make sure that the flow of the process is proper, algorithms and flowcharts are used which help us into developing a stepwise framework to achieve the main goal.

## What is an Algorithm?

To write a logical step-by-step method to solve the identified problem is called algorithm, in other words, an algorithm is a procedure for solving problems. In order to solve a mathematical or computer problem, this is the first step of the procedure. An algorithm includes calculations, reasoning and data processing. Algorithms can be presented by natural languages, pseudocode and flowcharts, etc.

## Activity

**Goal:** To give a glimpse of how to write a step by step algorithm for any problem/process in a bidirectional manner.

To understand algorithms better, let us take an example of the process of making instant noodles.

Basic steps to make any instant noodles are:

For Techno India NJR Institute of Technology ulzai Pankaj Kumar Borwa (Principal)

Can you think of other ways to make instant noodles? Write them down.

Challenge Time

Before we jump into challenging ourselves, let us go through some ground rules for this activity:

For Techno India NJR Institute of Technology Pankaj Kumar Porwa (Principal)

	GRO RUI	UND LES	
This is an individual Do not discuss your a with your peer	activity. answers s.	Think which a accomp vary fro	of various ways in a challenge could be lished. Solutions can om person to person.

Write algorithms for the challenges given.

Now, exchange your attempts with your friend and see what procedure have they followed for the same tasks.

Did you notice any difference?

Yes! Write the differences below.	No! How are they so similar?	

Re-look at your own algorithms now. Do you wish to make any changes to it? Is there a need to add/subtract step(s) in it? Take your time and make the necessary changes if required.

**Conclusion:** Through this activity, we understood:

- 1. How to divide a task into several sub-tasks and the advantage of doing so.
- 2. There can be multiple approaches in terms of the number of sub-tasks or the methods used in sub-tasks to solve a problem and the one which is the simplest and the most efficient should be chosen above all.

## What is a flowchart?

A flowchart is the graphical or pictorial representation of an algorithm with the help of different symbols, shapes and arrows in order to demonstrate a process or a program. While computers work with numbers at ease, humans need visual representations to understand the information well and communicate it effectively. Thus, flowcharts are used to break a process into smaller parts and elaborate it using visual representations.

Several standard graphics are applied in a flowchart:

For Techno India NJR Institute of Technology UIZAIO

Principal

Terminal Box	Input / Output	Process /	Decision	Connector /
(Start / End)		Instruction		Arrow

The graphics above represent different parts of a flowchart. The process in a flowchart can be expressed through boxes and arrows with different sizes and colors. In a flowchart, we can easily highlight a certain element and the relationships between each part. Let us take a look as to how can we use flowcharts to represent algorithms.

How to Use Flowcharts to Represent Algorithms

Now that we have the definitions of algorithm and flowchart, how do we use a flowchart to represent an algorithm? Let us take a look at given examples and see how they work.

Example 1: Print 1 to 20:

## Algorithm:

Step 1: Initialize X as 0,

Step 2: Increment X by 1,

Step 3: Print X,

**Step 4:** If X is less than 20 then go back to step 2.

## Flowchart:

For Techno India NJR Institute of Technology

Example 2: Convert Temperature from Fahrenheit (°F) to Celsius (°C)

ALGORITHM

**FLOWCHART** 

Step 1: Read temperature in

Fahrenheit

**Step 2:** Calculate temperature with formula C=5/9\*(F-32)

Step 3: Print C

## Challenge time!

Let us practice what we have learnt so far. Write algorithms and draw flowcharts for the tasks given below.

TASK 1: How to check whether the input number is prime or not?

TASK 2: How does a traffic signal work?

TASK 3: How to make an ATM transaction?

TASK 4: How to check if a light bulb is working or not?

TASK 5: How to win a Rock, Paper, Scissors Game – To know more about this game, go to <u>https://www.wikihow.com/Play-Rock,-Paper,-Scissors</u>

## Test Your Knowledge

Q1) What is an algorithm?

Q2) What is a flowchart?

Q3) List down all the standard graphics for making a flowchart.

For Techno India NJR Institute of Technology Can ST CT Zai CV Dr. Pankaj Kumary Borwa Principal

## Chapter 2: Introduction to Python

In the previous section, you learnt about the different methodologies for programming. A programming language is a formal language that specifies a set of instructions that can be used to produce various kinds of output.

In simple Words, a programming language is a vocabulary and set of grammatical rules for instructing a computer to perform specific tasks. Though there are many different programming languages such as BASIC, Pascal, C, C++, Java, Haskell, Ruby, Python, etc. we will study Python in this course.

## What is a program?

A computer program is a collection of instructions that perform a specific task when executed by a computer. It is usually written by a computer program in a programming language.

Before getting into understanding more about Python, we need to first understand what is Python and why we need to use Python?

## What is Python?

For Techno India NJR Institute of Technology

## Why Python for AI?

Artificial intelligence is the trending technology of the future. You can see so many applications around you. If you as an individual can also develop an AI application, you will require to know a programming language. There are various programming languages like Lisp, Prolog, C++, Java and Python, which can be used for developing applications of AI.Out of these, Python gains a maximum popularity because of the following reasons:

## Applications of Python

Python is used for a large number of applications. Some of them are mentioned below:

For Techno India NJR Institute of Technology

## Getting started with Python

Python is a cross-platform programming language, meaning, it runs on multiple platforms like Windows, MacOS, Linux and has even been ported to the Java and .NET virtual machines.

To write and run Python program, we need to have Python interpreter installed in our computer.

Downloading and Setting up Python for use

- Download Python from **python.org** using link **python.org/downloads**
- Select appropriate download link as per Operating System [Windows 32 Bit/64 Bit, Apple iOS]
- FOR EXAMPLE, for Windows 64 Bit OS
- Select the following link

• Download Windows x86-64 executable installer

Python IDLE installation

For Techno India NJR Institute of Technology tigh St UTZALON Dr. Pankaj Kumarz Borwa (Principal)

For Techno India NJR Institute of Technology Can St Cut 2010 Dr. Pankaj Kumar Borwa (Principal)

For Techno India NJR Institute of Technology Can St Can St

For Techno India NJR Institute of Technology Gan For Technology Dr. Pankaj Kumar2Porwa (Principal)

For Techno India NJR Institute of Technology Can St Can St

For Techno India NJR Institute of Technology Gan T Con Con Dr. Pankaj Kumar23 orwai (Principal)

## Run in the Integrated Development Environment (IDE)

When we install Python, an IDE named **IDLE** is also installed. We can use it to run Python on our computer.

IDLE (GUI integrated) is the standard, most popular Python development environment. IDLE is an acronym of Integrated <u>Development Environment</u>. It lets one edit, run, browse and debug Python Programs from a single interface. This environment makes it easy to write programs.

Python shell can be used in two ways, viz., interactive mode and script mode. Where Interactive Mode, as the name suggests, allows us to interact with OS; script mode lets us create and edit Python source file.

Interactive Mode

```
Python 3.6.5 Shell
                                                        X
File Edit Shell Debug Options Window Help
Python 3.6.5 (v3.6.5:f59c0932b4, Mar 28 2018, 17:00:18)
[MSC v.1900 64 bit (AMD64)] on win32
Type "copyright", "credits" or "license()" for more info
rmation.
>>> 3+10
13
>>> 2+4*10
42
>>> print("Hello Learner")
Hello Learner
>>> print("Result:", 40+5*100)
Result: 540
>>>
                                                         Ln: 11 Col: 4
```

You can see the above example, Python IDLE Shell account has >>> as Python prompt, where simple mathematical expressions and single line Python commands can be written and can be executed simply by pressing enter.

The first expression 3+10 written on the first Python prompt shows 13 as output in the next line.

The second expression 2+4\*10 written on the second Python prompt shows 42 as output in the next line.

The third statement print("Hello Learner") written on the third Python prompt shows Hello Learner as output in the next line.

The third statement print("Result:", 40+5\*100) written on the fourth Python prompt shows Result: as output in the next line.

For Techno India NJR Institute of Technology Technol Constitute of Technology Dr. Pankaj Kumar<u>P</u>orwa (Principal)

#### Try Yourself

- 1. Find the result of (75+85+65)/3 i.e. the average of three marks
- 2. Find the result of 22/7 \* 5 \* 5 i.e. the area of circle having radius as 5
- 3. Find the result of "RAVI"+"Kant"
- 4. Find the result of "###" \* 3

## Script Mode

In script mode, we type Python program in a file and then use the interpreter to execute the content from the file. Working in interactive mode is convenient for beginners and for testing small pieces of code, as we can test them immediately. But for coding more than few lines, we should always save our code so that we may modify and reuse the code.

**Note:** Result produced by Interpreter in both the modes, viz., Interactive and script mode is exactly the same.

Python Script/Program: Python statements written in a particular sequence to solve a problem is known as Python Script/Program.

To write a Python script/program, we need to open a new file - **File** >> **New File**, type a sequence of Python statements for solving a problem, save it with a meaningful name - **File** >> **Save**, and finally **Run** the program to view the output of the program.

For Techno India NJR Institute of Technology ST UTZAION Pankaj Kumarzborw (Principal)

Now, type your first Python Program

```
CBSE1.py - C:/Python37/Lib/idlelib/CBSE1.py (3.7.3)
File Edit Format Run Options Window Help
#Python Program 1
print("Hello")
Name="Sam"
print("Learner ",end="")
print(Name)
A=50
B=300
print(A," Times ", B," is ",A*B)
```

## **Code Explanation:**

Line 1 in the above code starting with # is a comment line, which means the line is non-executable and it is only for the programmer's reference.

Line 2 will simply display

#### Hello

Line 3 will assign a string value "Sam" to a variable Name

Line 4 will display Learner and will allow the next output to get displayed in the same line

Line 5 will display Sam in the same line as Learner

Line 6 will assign an integer 50 to a variable A

Line 7 will assign an integer **300** to a variable **B** 

Line 8 will display 50 times 300 is 15000

So, the complete output of the Python Code will be

#### Hello Learner Sam 50 times 300 is 15000

For Techno India NJR Institute of Technology

## Python Statement and Comments

In this section we will learn about Python statements, why indentation is important and how to use comments in programming.

## **Python Statement**

Instructions written in the source code for execution are called statements. There are different types of statements in the Python programming language like Assignment statement, Conditional statement, Looping statements etc. These help the user to get the required output. For example, n = 50 is an assignment statement.

#### **Multi-line statement**

In Python, end of a statement is marked by a newline character.

However, Statements in Python can be extended to one or more lines using parentheses (), braces {}, square brackets [], semi-colon (;), continuation character slash (\). When we need to do long calculations and cannot fit these statements into one line, we can make use of these characters.

Examples:

Type of Multi-line Statement	Usage
Using Continuation	s = 1 + 2 + 3 +
Character (/)	4 + 5 + 6 + \ 7 + 8 + 9
Using Parentheses ()	n = (1 * 2 * 3 + 4 - 5)
Using Square Brackets []	<pre>footballer = ['MESSI',                 'NEYMAR',                 'SUAREZ']</pre>
Using braces {}	$\mathbf{x} = \{1 + 2 + 3 + 4 + 5 + 6 + 7 + 8 + 9\}$
Using Semicolons (;)	<pre>flag = 2; ropes = 3; pole = 4</pre>

## **Python Comments**

A **comment** is text that doesn't affect the outcome of a code, it is just a piece of text to let someone know what you have done in a program or what is being done in a block of code.

In Python, we use the hash (#) symbol to start writing a comment.

For Techno India NJR Institute of Technology Tan J Car CA Dr. Pankaj Kumar<u>P</u>orwa (Principal)

Single line	Multi Line	
Comments	Comments	
#Defining a variable to store number.	This is an example code.	
a = 10	This is to learn Python for Al	
fb = "messi" #Store Messi as value in fb	This is an example code. This is to learn Python for Al	

## Python Keywords and Identifiers

In this section, we will learn about keywords (reserved words in Python) and identifiers (names given to variables, functions, etc.).

## Keywords

Keywords are the reserved words in Python used by Python interpreter to recognize the structure of the program.

For Techno India NJR Institute of Technology Gan T CT 201 CM Dr. Pankaj Kumar 800 (Principal)

The list of all the keywords is given below.

Keywords in Python				
False	class	finally	is	return
None	continue	for	lambda	try
True	def	from	nonlocal	while
and	del	global	not	with
as	elif	if	or	yield
assert	else	import	pass	
break	except	in	raise	

For Techno India NJR Institute of Technology <u>un</u>J Dr. Pankaj Kumar29crwa' (Principal)

## An identifier is a name given to entities like class, functions, variables, etc. It helps to differentiate one entity from another.

Identifiers can be a combination of letters in lowercase (a to z) or uppercase (A to Z) or digits (0 to 9) or an underscore \_.

An identifier cannot start with a digit. 1variable is invalid, but variable1 is perfectly fine.

identifiers.

Keywords cannot be used as

We cannot use special symbols like !, @, #, \$, % etc. in our identifier.

Identifier can be of any length.

## Note:

Python is a case-sensitive language. This means, Variable and variable are not the same. Always name identifiers that make sense.

While, c = 10 is valid. Writing count = 10 would make more sense and it would be easier to figure out what it does even when you look at your code after a long gap.

Multiple words can be separated using an underscore, for example this\_is\_a\_long\_variable

## Variables and Datatypes

#### Variables

A variable is a named location used to store data in the memory. It is helpful to think of variables as a container that holds data which can be changed later throughout programming. For example,

x = 42y = 42

For Techno India NJR Institute of Technology Tan J UT Zal CA Dr. Pankaj KumarzBorwa (Principal)

These declarations make sure that the program reserves memory for two variables with the names x and y. The variable names stand for the memory location. It's like the two shoeboxes, which you can see in the picture. These shoeboxes are labelled with x and y and the corresponding values are stored in the shoeboxes. Like the two shoeboxes, the memory is empty as well at the beginning.

#### Note:

Assignment operator is used in Python to assign values to variables. For example, a = 5 is a simple assignment operator that assigns the value 5 on the right to the variable a on the left.

Task	Sample Code	Output	
Assigning a value to a variable	Website = "xyz.com" print(Website)	xyz.com	
Changing value of a	Website = "xyz.com"	xyz.com	
variable	print(Website)	abc.com	
	Website = "abc.com"		
	print(Website)		
Assigning different values	a,b,c=5, 3.2,	5	
to different variables	"Hello"	3.2	
	print(a)	Hello	V.Dolondary
	print(b)	India NJR Institute	of recimers of
		For TECITIO India In Const Con	Encipal)

Examples on Variables:

	print(c)	
Assigning same value to	x=y=z= "Same"	Same
different variable	print(x)	Same
	print(y)	Same
	print(z)	

## Constants:

A constant is a type of variable whose value cannot be changed. It is helpful to think of constants as containers that hold information which cannot be changed later.

Non technically, you can think of constant as a shoe box with a fixed size of shoe kept inside which cannot be changed after that.

## Assigning Value to a constant in Python

In Python, constants are usually declared and assigned on a module. Here, the module means a new file containing variables, functions etc. which is imported to the main file. Inside the module, constants are written in all capital letters and underscores separating the words.

Example : Declaring and assigning value to a constant

• Create a info.py

```
NAME = "Ajay"
AGE = 24
```

• Create a main.py

import info

print(info.NAME)
print(info.AGE)

• When you run the program the output will be,

Ajay 24

For Techno India NJR Institute of Technology Tign I and Area and Dr. Pankaj KumargPorwa (Principal)

In the above program, we create a constant.py module file. Then, we assign the constant value to PI and GRAVITY. After that, we create a main.py file and import the constant module. Finally, we print the constant value.

Note: In reality, we don't use constants in Python. The global or constants module is used throughout the Python programs.

## Rules and Naming convention for variables and constants

## Datatypes

Every value in Python has a datatype. Since everything is an object in Python programming, data types are actually classes and variables are instance (object) of these classes.

There are various data types in Python. Some of the important types are mentioned below in the image

**Python Data types** 

For Techno India NJR Institute of Technology Tigh J Constant Contrology (Principal)

#### 1) Python Numbers

Number data type stores Numerical Values. These are of three different types:

a) Integer & Longb) Float / floating point

#### Integer & Long Integer

Range of an integer in Python can be from -2147483648 to 2147483647, and long integer has unlimited range subject to available memory.

Integers are the whole numbers consisting of + or - sign with decimal digits like 100000, -99, 0, 17. While writing a large integer value, don't use commas to separate digits. Also, integers should not have leading zeros.

#### **Floating Point:**

Numbers with fractions or decimal point are called floating point numbers.

A floating-point number will consist of sign (+,-) sequence of decimals digits and a dot such as 0.0, -21.9, 0.98333328, 15.2963. These numbers can also be used to represent anumber in engineering/ scientific notation.

-2.0 x  $10^5$  will be represented as -2.0e5 2.0X10<sup>-5</sup> will be 2.0E-5

#### 2) None

This is special data type with single value. It is used to signify the absence of value/false in a situation. It is represented by **None**.

#### 3) Sequence

A sequence is an ordered collection of items, indexed by positive integers. It is a combination of mutable and non-mutable data types. Three types of sequence data type available in Python are:

- a) Strings
- b) Lists
- c) Tuples

#### String

String is an ordered sequence of letters/characters. They are enclosed in single quotes (' ') or double (" "). The quotes are not part of string. They only tell the computer where the string constant begins and ends. They can have any character or sign, including space in them.

#### Lists

List is also a sequence of values of any type. Values in the list are called elements / items. These are indexed/ordered. List is enclosed in square brackets.

Example:

For Techno India NJR Institute of Technology Tan J and Ang Dr. Pankaj Kumarggorwa (Principal)

dob = [19, "January", 1990]

#### **Tuples:**

Tuples are a sequence of values of any type, and are indexed by integers. They are immutable. Tuples are enclosed in ().

Example:

t = (5, 'program', 2.5)

#### 4) Sets

Set is an unordered collection of values, of any type, with no duplicate entry.

Example:

>>> a = {1,2,2,3,3,3} >>> a {1,2,3}

#### 5) Mapping

This data type is unordered. Dictionaries fall under Mappings.

#### **Dictionaries**

<u>Dictionary</u> is an unordered collection of key-value pairs. It is generally used when we have a huge amount of data. Dictionaries are optimized for retrieving data. We must know the key to retrieve the value.

In Python, dictionaries are defined within braces {} with each item being a pair in the form key: value. Key and value can be of any type.

#### Example

```
>>> d = {1:'Ajay','key':2}
>>> type(d)
<class 'dict'>
```

For Techno India NJR Institute of Technology Tigh J UI Zal CV Dr. Pankaj Kumar 3500 W2 (Principal)

## Python Operators I

Operators are special symbols which represent computation. They are applied on operand(s), which can be values or variables. Same operators can behave differently on different data types. Operators when applied on operands form an expression. Operators arecategorized as Arithmetic, Relational, Logical and Assignment. Value and variables when used with operator are known as operands.

## Arithmetic Operators

Operator	Meaning	Expression	Result
+	Addition	10 + 20	30
-	Subtraction	30 - 10	20
*	Multiplication	30 * 100	300
/	Division	30 / 10	20.0
		1 / 2	0.5
	Integer Division	25 // 10	2
		1 // 2	0
olo	Remainder	25 % 10	5
**	Raised to power	3 ** 2	9

## Python Input and Output

## Python Output Using print() function

We use the print() function to output data to the standard output device (screen). We can also output data to a file. An example is given below.

```
a = "Hello World!"
print(a)
```

The output of the above code will be:

a = 20 b = 10 print(a + b)	30
print(15 + 35)	50
print("My name is Kabir")	My name is Kabir
a = "tarun" print("My name is :",a)	My name is : tarun
x = 1.3	x =
print("x = /n", x)	1.3
<pre>m = 6 print(" I have %d apples",m)</pre>	I have 6 apples

### User input

In all the examples till now, we have been using the calculations on known values (constants). Now let us learn to take user's input in the program. In python, input() function is used for the same purpose.

Syntax	Meaning
<string variable="">=input(<string>)</string></string>	For string input
<integer variable="">=int(input(<string>))</string></integer>	For integer input
<float variable="">=float(input(<string>))</string></float>	For float (Real no.) input

## **Type Conversion**

The process of converting the value of one data type (integer, string, float, etc.) to another data type is called type conversion. Python has two types of type conversion.

- 1. Implicit Type Conversion
- 2. Explicit Type Conversion

### Implicit Type Conversion

In Implicit type conversion, Python automatically converts one data type to another data type. This process doesn't need any user involvement.

For Techno India NJR Institute of Technology Tan J and Dr. Pankaj Kumarz Porwa (Principal)

Example:

```
# Code to calculate the Simple Interest
principle_amount = 2000
roi = 4.5
time = 10
simple_interest = (principle_amount * roi * time)/100
print("datatype of principle amount : ", type(principle_amount))
print("datatype of rate of interest : ", type(roi))
print("value of simple interest : ", simple_interest)
print("datatype of simple interest : ", type(simple_interest))
```

When we run the above program, the output will be

datatype of principle amount : <class 'int'>
datatype of rate of interest : <class 'float'>
value of simple interest : 900
datatype of simple interest : <class 'float'>

In the above program,

- We calculate the simple interest by using the variable priniciple\_amount and roi with time divide by 100
- We will look at the data type of all the objects respectively.
- In the output we can see the datatype of principle\_amount is an integer, datatype of roi is a float.
- Also, we can see the simple\_interest has float data type because Python always converts smaller data type to larger data type to avoid the loss of data.

For Techno India NJR Institute of Technology Tign I Technology Dr. Pankaj Kumar380rwa (Principal)

Example	Sample Output	Explanation
Code		
a = 10	File "cbse2.py", line 3, in	The output shows an
b = "Hello"	<module></module>	error which says that
print(a+b)	print(a+b)	we cannot add integer
	TypeError: unsupported	and string variable
	operand type(s) for +:	types using implicit
	'int' and 'str'	conversion
c = 'Ram'	RamRamRam	The output shows that
N = 3		the string is printed
print(c*N)		3 times when we use a
		multiply operator with
		a string.
x = True	11	The output shows that
y = 10		the boolean value x
print(x + 10)		will be converted to
		integer and as it is
		true will be
		considered as 1 and
		then give the output.
m = False	23	The output shows that
n = 23		the boolean value m
print(n - m)		will be converted to
		integer and as it is
		false will be
		considered as 0 and
		then give the output.

#### Try It Yourself:

- 1) Take a Boolean value and add a string to it
- 2) Take a string and float number and try adding both
- 3) Take a Boolean and a float number and try adding both.

## Explicit Type Conversion

In Explicit Type Conversion, users convert the data type of an object to required data type. We use the predefined functions like int(), float(), str(), etc to perform explicit type conversion.

This type of conversion is also called typecasting because the user casts (changes) the data type of the objects.

For Techno India NJR Institute of Technology Technol Constitute of Technology Dr. Pankaj Kumarggorwa (Principal)

#### Syntax:

(required\_datatype)(expression)

Typecasting can be done by assigning the required data type function to the expression. Example: Adding of string and an integer using explicit conversion

```
Birth_day = 10
Birth_month = "July"
print("data type of Birth_day before type casting :", type(Birth_day))
print("data type of Birth_month : ", type(Birth_month))
Birth_day = str(Birth_day)
print("data type of Birth_day after type casting :",type(Birth_day))
Birth_date = Birth_day + Birth_month
print("birth date of the student : ", Birth_day)
print("data type of Birth_date : ", type(Birth_date))
```

When we run the above program, the output will be

```
data type of Birth_day before type casting : <class 'int'>
data type of Birth_month : <class 'str'>
data type of Birth_day after type casting : <class 'str'>
birth date of the student : ' 10 July '
data type of Birth_date : <class 'str'>
```

In above program,

- We add Birth\_day and Birth\_month variable.
- We converted Birth\_day from integer(lower) to string(higher) type using str() function to perform the addition.
- We got the Birth\_date value and data type to be string.

For Techno India NJR Institute of Technology Tigh J Line Kumara Porwa (Principal)

Example Code	Sample Output	Explanation
a = 20	20 Apples	Writing str(a) will
b = "Apples"		convert integer a
<pre>print(str(a) + b)</pre>		into a string and
		then will add to
		the string b.
x = 20.3	30	Writing int(x) will
y = 10		convert a float
<pre>print(int(x) + y)</pre>		number to integer
		by just considering
		the integer part of
		the number and then
		perform the
		operation.
m = False	1	Writing Bool() will
n = 5		convert the integer
<pre>print(Bool(n) + m)</pre>		value to Boolean.
		If it is zero then
		it is converted to
		False, else to True
		for all other
		cases.

#### Try it yourself:

1) Take a Boolean value "False" and a float number "15.6" and perform the AND operation on both

2) Take a string "Zero" and a Boolean value "True" and try adding both by using the Bool() function.

3) Take a string "Morning " and the float value "90.4" and try and add both of them by using the float() function.

Perform the above mentioned Try it Yourself in the lab and write down the observations to be discussed later in the class.

#### Note:

There is no **difference** in **single** or **double quoted** string. Both representations can be used interchangeably. However, if either **single** or **double quote** is a part of the string itself, then the string must be placed in **double** or **single quotes** respectively.

For Techno India NJR Institute of Technology Gan J CT 201 CM Dr. Pankaj Kumar4Porwa (Principal)

## Python Operators II

## Comparison operators

Operator	Meaning	Expression	Result
>	Greater Than	20 > 10	True
		15 > 25	False
<	Less Than	20 < 45	True
		20 < 10	False
==	Equal To	5 == 5	True
		5 == 6	False
! =	Not Equal to	67 != 45	True
		35 != 35	False
>=	Greater than or Equal to	<b>45 &gt;= 45</b>	True
		23 >= 34	False
<=	Less than or equal to	13 <= 24	True
		13 <= 12	False

Comparison operators are used to compare values. It either returns True or False according to the condition.

## Logical operators

Operator	Meaning	Expression	Result
And	And operator	True and True	True
		True and False	False
Or	Or operator	True or False	True
		False or False	False
Not	Not Operator	not False	True
		not True	False

Logical operators are the and, or, not operators.

For Techno India NJR Institute of Technology Can I and Charles and Dr. Pankaj Kumar4Porwat (Principal)

Assignment operators

Operator	Expression	Equivalent to
=	<b>X=</b> 5	X = 5
+=	x +=5	$\mathbf{X} = \mathbf{X} + 5$
-=	x -= 5	$\mathbf{X} = \mathbf{X} - 5$
*=	X *= 5	$\mathbf{X} = \mathbf{X} * 5$
/=	x /= 5	$\mathbf{x} = \mathbf{x} / 5$

Assignment operators are used in Python to assign values to variables.

## Let's Practice

print("Perimeter:", Perimeter)

For Techno India NJR Institute of Technology धैकज परिवाल Dr. Pankaj Kumar43orwa (Principal)

Try writing your code	Sample Output
<pre># To calculate Area of a triangle # with Base and Height</pre>	Base:20 Height:10 Area:100
<pre># To calculating average marks # of 3 subjects</pre>	English:80 Maths :75 Science:85 Total Marks : 240 Average Marks: 80.0
<pre># To calculate discounted amount # with discount %</pre>	Amount: 5000 Discount%:10 Discount:500 Discounted Amt:4500
<pre># To calculate Surface Area and Volume # of a Cuboid</pre>	Length:20 Breadth:10 Height:15 Surface Area:1300 Volume:3000

Q2) What are the different modes for coding in python?

Q3) What are comments in python ? List down the various types of comments.

Q4) What are the different properties of an identifier ?

Q5) What are the rules for naming of variables and constants

Q6) Explain python input and output with the help of an example.

Q7) What is type conversion ? Explain the types of type conversion with the help of an example.

Q8) What is a variable? Give example.

For Techno India NJR Institute of Technology Transf Transf Dr. Pankaj Kumar440rwa (Principal)

# Chapter 3 - Introduction to tools for AI

### Recap

Till now we have learnt about flowcharts & algorithms, Python programming language, and how to run programs in IDLE, what are packages and modules, and how it helps us in better and faster coding. Now, we will learn and explore new tools which will help us with better understanding, faster debugging of codes, and a lot more.

## Introduction to Anaconda

We have explored about 3 major domains of AI: Data, NLP and CV. It often happens that while writing a code, these domains have different *packages* which need to be installed. Though we can install them all in IDLE, it is difficult to manage them all.

**Anaconda** is a <u>free and open-source</u> distribution of the <u>Python</u> language for <u>scientific</u> <u>computing</u> (<u>data science</u>, <u>machine learning</u> applications, large-scale data processing, <u>predictive analytics</u>, etc.), that aims to simplify <u>package management</u> and deployment. It provides the facility to create different *virtual environments*, each having its own packages and settings, as per user's need.

**Anaconda Navigator** is a desktop graphical user interface(GUI) included in Anaconda that allows you to launch applications and easily manage conda packages, environments and channels without the need to use command line commands.

### How to install Anaconda?

Anaconda distribution is open source and is available for Windows, Linux and Mac OS. Here are the steps of how to download and install Anaconda for windows.

1) Log on to <u>https://www.anaconda.com/distribution/</u>

O ANACONDA.	Products	Why Anaconda	? Solution	ns Resou	rces Con	ipany Down	Noad Q
Anaconda Distribution The World's Most Popular Python/R Data Science Platform Do	wnload					X	
The open-source Anaconda Distribution is the easiest way to perform Pyt data science and machine learning on Linux. Windows, and Mac OS X W over 15 million users worldwide, it is the industry standard for developing testing, and training on a single machine, enabling <i>individual data scienci</i> . Guickly download 1500° Python/R data science packages . Manage libraries, dependencies, and environments with Conda . Develop and train machine learning and deep learning models with learn, TensorFilow, and Theano . Analyze data with scalability and performance with Dask, NumPy, p and Numba . For Techno India NJR Institute of Technology Technology Dr. Pankaj Kumar48 principal)

12) Click on "Finish". Your Anaconda setup is complete!

You can also install anaconda for MacOS and Linux from <a href="https://www.anaconda.com/distribution/">https://www.anaconda.com/distribution/</a>

#### What did we install?

Anaconda Prompt- Anaconda's Command Line Interface.

Anaconda Prompt is a Python CLI where we can create different virtual environments and install packages into them as per our need.

Anaconda prompt can be opened by writing "Anaconda Prompt" in windows search bar.

For Techno India NJR Institute of Technology Tign I and Algoria Dr. Pankaj Kumar4goriva (Principal)

For Techno India NJR Institute of Technology Can St Can S

Note the **(base)** written at the beginning of the line, it shows that the active environment is base, as it is the default environment.

## Jupyter Notebook

https://www.dataquest.io/blog/jupyter-notebook-tutorial/ https://realpython.com/jupyter-notebook-introduction/ https://jupyter.readthedocs.io/en/latest/glossary.html#term-kernel https://www.dataquest.io/blog/jupyter-notebook-tutorial/

### Introduction

The Jupyter Notebook is an incredibly powerful tool for interactively developing and presenting AI related projects. The Jupyter project is the successor to the earlier IPython Notebook, which was first published as a prototype in 2010. Although it is possible to use many different programming languages within Jupyter Notebooks, Python remains the most commonly used language for it. In other words, we can say that the Jupyter Notebook is an open source web application that you can use to create and share documents that contain live code, equations, visualizations, and text.

### What is a Notebook?

Before we dive deep into Jupyter Notebooks, let us first understand what a notebook is. A notebook integrates code and its output into a single document that combines visualizations, narrative text, mathematical equations, and other rich media. This intuitive workflow promotes iterative and rapid development, making notebooks an increasingly popular choice at the heart of contemporary data science, analysis, and increasingly science at large.

Can ST CT Zai on Dr. Pankaj KumarsPorwa

### Installing Jupyter Notebook

The easiest way to install and start using Jupyter Notebook is through Anaconda. Anaconda is the most widely used Python distribution for data science and comes pre-loaded with all the most popular libraries and tools. With Anaconda, comes the Anaconda Navigator through which we can scroll around all the applications which come along with it.

### Working with Jupyter Notebook

To work with Jupyter Notebook, it is necessary to have a kernel on which it operates. A kernel provides programming language support in Jupyter. IPython is the default kernel for Jupyter Notebook. Therefore, whenever we need to work with Jupyter Notebook in a virtual environment, we first need to install a kernel inside the environment in which the jupyter notebook would run.

To install the kernel, Open Anaconda Prompt and execute the following command:

```
conda install jupyter nb_conda ipykernel
```

Here, Jupyter is an extension to the Jupyter Notebook which gets installed. Ipykernel is a powerful and interactive Python shell and a jupyter kernel to work with python code in Jupyter Notebooks and nb\_conda refers to notebook conda which is an extension to jupyter kernel to set the kernel for a notebook's execution. Once the installation is done, write the following command to open the Jupyter Notebook.

jupyter notebook

The Jupyter Notebook opens in the default browser with <u>http://localhost:8888/tree</u> URL.

Home Home X + V		J ×
→ O ଲ ⊙ localhost8888/tree		e

In this page, click on New and select Python3 which would open a new Jupyter notebook with Python3 as the default language.

Clicking on Python3 opens a new Jupyter notebook:

Notebook Interface - Explained!

As we have learnt, Jupyter Notebook is a Graphical User Interface (GUI) which means that the Notebook interface contains a lot of easily-accessible tools for making the work easier as all of them are clicks away.

Let us take a tour around the Notebook and understand its features.

#### 1. Menu Bar

For Techno India NJR Institute of Technology Technol United States Dr. Pankaj Kumarggorwa (Principal)

Jupyter Notebook has its own Menu bar which has the following options:

1. File: In the file menu, you can create a new Notebook or open a pre-existing one. This is also where you would go to rename a Notebook. I think the most interesting menu item is the *Save and Checkpoint* option. This allows you to create checkpoints that you can roll back to if you need to.

Jupyter New Notebook Last Checkpoint: 20 minutes ago (autosaved)							
File Edit View	Insert	Cell	Kernel	Widgets	Help		
New Notebook  Open	<b>↑ ↓</b>	N Run	C	▶ Code			
Make a Copy Save as Rename Save and Checkpoint							
Revert to Checkpoint 🕨							
Print Preview Download as							
Trusted Notebook							
Close and Halt							

2. Edit Menu: Here you can cut, copy, and paste cells. This is also where you would go if you wanted to delete, split, or merge a cell. You can reorder cells here too.

For Techno India NJR Institute of Technology Tan J Tan and Dr. Pankaj Kumarsporwa (Principal)

3. View menu: The *View* menu is useful for toggling the visibility of the header and toolbar. You can also toggle *Line Numbers* within cells on or off. This is also where you would go if you want to mess about with the cell's toolbar.

For Techno India NJR Institute of Technology Tan J and Angel Dr. Pankaj Kumarsporwa (Principal)

4. Insert menu: The *Insert* menu is just for inserting cells above or below the currently selected cell.

JUPYTET New Notebook Last Checkpoint: 26 minutes ago (autosaved)

File Edit View	Insert Cell Kernel Widgets Help
<b>B</b> + % & <b>B</b>	Insert Cell Above C ▶ Code ∨ Insert Cell Below
In []: 州	

5. Cell menu: The *Cell* menu allows you to run one cell, a group of cells, or all the cells. You can also go here to change a cell's type, although the toolbar is more intuitive for that. The other handy feature in this menu is the ability to clear a cell's output.

Upyter New Notebook Last Checkpoint: 27 minutes ago (autosaved)

File	Edit	View	Insert	Cell	Kernel	Widgets	5	Help

- Q2) What is a notebook ?
- Q3) How can one install jupyter notebook in anaconda prompt?
- Q4) Explain the different tools in a toolbar
- Q5) Why do we need to install a kernel before running jupyter notebook?

For Techno India NJR Institute of Technology Technology Dr. Pankaj KumarsBorwa (Principal)

# Chapter 4 - More About Lists and Tuples

## Introduction to Lists

As studied in the previous section, List is a sequence of values of any type. Values in the list are called elements / items. List is enclosed in square brackets.

Example:

#### a = [1,2.3,"Hello"]

List is one of the most frequently used and very versatile data type used in Python. A number of operations can be performed on the lists, which we will study as we go forward.

## How to create a list ?

In Python programming, a list is created by placing all the items (elements) inside a square bracket [], separated by commas.

It can have any number of items and they may be of different types (integer, float, string etc.).

#### **Example:**

```
#empty list
empty_list = []
#list of integers
age = [15,12,18]
#list with mixed data types
student_height_weight = ["Ansh", 5.7, 60]
```

Note: A list can also have another list as an item. This is called nested lists.

```
# nested list
student marks = ["Aditya", "10-A", [ "english",75]]
```

## How to access elements of a list?

A list is made up of various elements which need to be individually accessed on the basis of the application it is used for. There are two ways to access an individual element of a list:

- 1) List Index
- 2) Negative Indexing

For Techno India NJR Institute of Technology Ciensi Ul Zal CM

### List Index

A list index is the position at which any element is present in the list. Index in the list starts from 0, so if a list has 5 elements the index will start from 0 and go on till 4. In order to access an element in a list we need to use index operator [].

### **Negative Indexing**

Python allows negative indexing for its sequences. The index of -1 refers to the last item, -2 to the second last item and so on.

In order to access elements using negative indexing, we can use the negative index as mentioned in the above figure.

Task	Sample Code	Output
Accessing Using List Index	<pre>language = ['p','y','t','h','o','n'] print(my_list[0]) print(my_list[4])</pre>	p e
	<pre>language = ['p','y','t','h','o','n'] print(my_list[4.0])</pre>	Y Error! Only Integer can be used for indexing
Accessing Value in a nested list	<pre>n_list = ["Happy",[2,0,1,5]] print(n_list[0][1]) print(n_list[1][3])</pre>	A 5
Accessing using Negative Index	<pre>day = ['f','r','i','d','a','y'] print(a[-1]) print(a[-6])</pre>	Y f

For Techno India NJR Institute of Technology Canst al zal cu Dr. Pankaj Kumaroporwa (Principal)

## Adding Element to a List

We can add an element to any list using two methods :

- 1) Using append() method
- 2) Using insert() method
- 3) Using extend() method

Using append() method

Task	Sample Code	Output
Using append() method	List = [] print("Initial blank List: ") print(List) # Addition of Elements # in the List List.append(1) List.append(2) List.append(4) print("\nList after Addition : ") print(List)	Initial blank List: [] List after Addition: [1, 2, 4]
Using	<pre># Addition of List to a List List2 = ['Good', 'Morning'] List.append(List2) print("\nList after Addition of a List: ") print(List) # Creating a List</pre>	List after Addition of a List: [1, 2, 4, ['Good', 'Morning']]
insert() method	<pre># Oreacting a hist List = [1,2,3,4] print("Initial List: ") print(List) # Addition of Element at # specific Position # (using Insert Method) List.insert(3, 12) List.insert(0, 'Kabir') print("\nList after Insert Operation: ") print(List)</pre>	<pre>[1, 2, 3, 4] List after Insert Operation: ['Kabir', 1, 2, 3, 12, 4]</pre>
Using	# Creating a List	For Techno India NJR Institute of Techno

Dr. Pankaj Kumar Borwa' (Principal)

extend()	List = [1,2,3,4]	[1, 2, 3, 4]
method	print("initial List: ")	
	print(List)	List after Extend
		Operation:
	<pre># Addition of multiple</pre>	[1, 2, 3, 4, 8,
	elements	'Artificial',
	# to the List at the end	'Intelligence']
	<pre># (using Extend Method)</pre>	
	List.extend([8, 'Artificial',	
	'Intelligence'])	
	print("\nList after Extend	
	Operation: ")	
	print(List)	

Elements can be added to the List by using built-in append() function. Only one element at a time can be added to the list by using append() method, for addition of multiple elements with the append() method, loops are used. Tuples can also be added to the List with the use of append method because tuples are immutable. Unlike Sets, Lists can also be added to the existing list with the use of append() method.

### Using insert() Method

append() method only works for addition of elements at the end of the List, for addition of element at the desired position, insert() method is used. Unlike append() which takes only one argument, insert() method requires two arguments(position, value).

## Using extend() method

Other than append() and insert() methods, there's one more method for Addition of elements, extend(), this method is used to add multiple elements at the same time at the end of the list.

## Removing Elements from a List

Elements from a list can removed using two methods :

- 1) Using remove() method
- 2) Using pop() method

For Techno India NJR Institute of Technology Technol Constitute of Technology Dr. Pankaj Kumarogorwa (Principal)

Task	Sample Code	Output	
	# Creating a List	Intial List:	
Using	List = [1, 2, 3, 4, 5, 6,	[1, 2, 3, 4, 5, 6,	
remove()	7, 8, 9, 10, 11,12]	7, 8, 9, 10, 11,	
method	<pre>print("Intial List: ")</pre>	12]	
	print(List)		
		List after Removal:	
	<pre># Removing elements from List</pre>	[1, 2, 3, 4, 7, 8,	
	<pre># using Remove() method</pre>	9, 10, 11, 12]	
	List.remove(5)		
	List.remove(6)		
	print("\nList after Removal:		
	")		
	print(List)		
Using pop()	# Removing element from the	List after popping	
method	<pre># Set using the pop() method</pre>	an element:	
	List.pop()	[1, 2, 3, 4]	
	print("\nList after popping		
	an element: ")	List after popping	
	print(List)	a specific element:	
		[1, 2, 4]	
	# Removing element at a		
	<pre># specific location from the</pre>		
	<pre># Set using the pop() method</pre>		Fleme
	List.pop(2)		nte
	<pre>print("\nContent after pop ")</pre>		can
	print(List)		he

removed from the List by using built-in remove() function but an Error arises if element

doesn't exist in the set. <u>Remove()</u> method only removes one element at a time, to remove range of elements, iterator is used. The remove() method removes the specified item.

Note - Remove method in List will only remove the first occurrence of the searched element.

## Using pop() method

Pop() function can also be used to remove and return an element from the set, but by default it removes only the last element of the set, to remove an element from a specific position of the List, index of the element is passed as an argument to the pop() method.

For Techno India NJR Institute of Technology Tan J Tan J Dr. Pankaj Kumaroporwa (Principal)

## Slicing of a List

In Python List, there are multiple ways to print the whole List with all the elements, but to print a specific range of elements from the list, we use <u>Slice operation</u>. Slice operation is performed on Lists with the use of colon(:). To print elements from beginning to a range use [:Index], to print elements from end use [:-Index], to print elements from specific Index till the end use [Index:], to print elements within a range, use [Start Index: End Index] and to print whole List with the use of slicing operation, use [:]. Further, to print whole List in reverse order, use [::-1].

Task	Sample Code	Output
	<pre># Creating a List List= ['G','O','O','D','M','O',</pre>	Initial List: ['G','O','O','D','M', 'O', 'R','N','I','N','G'] Slicing elements in
Slicing	<pre>Sliced_List = List[3:8] print("\nSlicing elements in a range 3-8: ") print(Sliced_List)</pre>	a range 3-8: ['D', 'M', 'O', 'R', 'N']
	<pre># Print elements from a # pre-defined point to end Sliced_List = List[5:] print("Elements sliced from 5th element till the end: ") print(Sliced_List)</pre>	Elements sliced from 5th element till the end: ['M', 'O', 'R', 'N', 'I', 'N', 'G']
	<pre># Printing elements from # beginning till end Sliced_List = List[:] print("\nPrinting all elements F</pre>	Printing all elements using or Techno India NJR Institute of Technology

Cr. Pankaj Kumar<sub>6</sub>5<sup>orwa</sup> (Principal)

	using slice operation: ")	slice operation:
	<pre>print(Sliced_List)</pre>	
		['G','O','O','D','M',
		'O',
		'R','N','I','N','G']
Slicing	# Creating a List	Initial List:
using	List= ['G','O','O','D','M','O',	['G','O','O','D','M',
negative	'R','N','I','N','G']	'0',
index of list	print("Initial List: ")	'R','N','I','N','G']
	print(List)	, , , , ,
	# Drint clonents from beginning	
	# to a pro defined point using	Elements sliced
	Slice	till 6th element
	Sliced List = List[:-6]	from last:
	print("\nElements sliced till 6th	['G','O','O','D','M',
	element from last: ")	'0']
	<pre>print(Sliced_List)</pre>	-
	<pre># Print elements of a range</pre>	Elements sliced
	<pre># using negative index List</pre>	from index -6 to -1
	slicing	['R', 'N', 'I',
	Sliced_List = List[-6:-1]	
	print("\nElements sliced from	N, G]
	print(Sliged List)	
	# Printing elements in reverse	Printing List in
	# using Slice operation	
	Sliced List = List[::-1]	reverse:
	print("\nPrinting List in reverse:	• • • • • • • • • • • • •
	- ")	['G','N','I','N','R',
	<pre>print(Sliced_List)</pre>	'0',
		'M','D','O','O','G']

For Techno India NJR Institute of Technology Ten I and Charles Dr. Pankaj Kumar (Principal)

### List Methods

Some of the other functions which can be used with lists are mentioned below:

Python List Methods
append() - Add an element to the end of the list
extend() - Add all elements of a list to the another list
insert() - Insert an item at the defined index
remove() - Removes an item from the list
pop() - Removes and returns an element at the given index
clear() - Removes all items from the list
index() - Returns the index of the first matched item
count() - Returns the count of number of items passed as an argument
sort() - Sort items in a list in ascending order
reverse() - Reverse the order of items in the list
copy() - Returns a shallow copy of the list

Now that you have learnt the basic concepts of Lists in python, it is time for us to get our hands on to practicing about list using a Jupyter Notebook.

To open jupyter notebook, go to start menu and open anaconda prompt and **jupyter notebook** in it.

## Let's Practice

Go through the List Jupyter Notebook to get an experiential learning experience for Lists. To download the Jupyter Notebook, go to the following link : <u>http://bit.ly/lists\_jupyter</u>

#### Note:

To open Jupyter notebook, go to start menu  $\rightarrow$  open anaconda prompt  $\rightarrow$  write "jupyter notebook"

## Introduction to Tuples

Tuple is a collection of Python objects which is ordered and unchangeable. The sequence of values stored in a tuple can be of any type, and they are indexed by integers. Values of a tuple are syntactically separated by 'commas'. Although it is not necessary, it is more For Technology

Const CT 201 cv Const CT 201 cv Dr. Pankaj Kumaro Porwa (Principal)

common to define a tuple by closing the sequence of values in parentheses. This helps in understanding the Python tuples more easily.

Example

fruits = ("apple", "banana", "cherry")

## How to Create a tuple ?

In Python, tuples are created by placing sequence of values separated by 'comma' with or without the use of parentheses for grouping of data sequence. It can contain any number of elements and of any datatype (like strings, integers, list, etc.).

Example
#Creating an empty Tuple
Tuple1 = ()
#Creating a Tuple with the use of string
Tuple1 = ('Artificial', 'Intelligence')
#Creating a Tuple with Mixed Datatype
Tuple1 = (5, 'Artificial', 7, 'Intelligence')

### Accessing of Tuples

We can use the index operator [] to access an item in a tuple where the index starts from 0. So, a tuple having 6 elements will have indices from 0 to 5. Trying to access an element outside of tuple (for example, 6, 7,...) will raise an IndexError. The index must be an integer; so, we cannot use float or other types. This will result in TypeError.

Example

```
fruits = ("apple", "banana", "cherry")
print(fruits[1])
```

The above code will give the output as "banana"

## **Deleting a Tuple**

Tuples are immutable and hence they do not allow deletion of a part of it. Entire tuple gets deleted by the use of del() method.

Example

num = (0, 1, 2, 3, 4)del num

For Techno India NJR Institute of Technology Canst Ulzarov Dr. Pankaj Kumar680rwa

## Test Your Knowledge

- Q1) What is the difference between a list and a tuple ?
- Q2) Explain the different ways of slicing a list with a help of an example.
- $\ensuremath{\mathsf{Q3}}\xspace$  ) What is negative indexing ? Explain with an example.
- Q4) Mention the methods to remove elements from a list.
- Q5) What is the method to delete an element from a tuple?

For Techno India NJR Institute of Technology Tan J and Dr. Pankaj Kumar Borwa (Principal)

# Chapter 5 - Flow of Control and Conditions

In the programs we have seen till now, there has always been a series of statements faithfully executed by Python in exact top-down order. What if you wanted to change the flow of how it works? For example, you want the program to take some decisions and do differentthings depending on different situations, such as printing 'Good Morning' or 'Good Evening' depending on the time of the day?

As you might have guessed, this is achieved using control flow statements. There are three control flow statements in Python - if, for and while.

## If Statement

On the occasion of World Health Day, one of the schools in the city decided to take an initiative to help students maintain their health and be fit. Let's observe an interesting conversation happening between the students when they come to know about the initiative.

For Techno India NJR Institute of Technology Ciensi Ulzaren Dr. Pankaj Kumar-Borwa (Principal

There come situations in real life when we need to make some decisions and based on these decisions, we need to decide what should we do next. Similar situations arise in programming also where we need to make some decisions and based on these decisionswe will execute the next block of code.

Decision making statements in programming languages decide the direction of flow of program execution. Decision making statements available in Python are:

- if statement
- if..else statements
- if-elif ladder

For Techno India NJR Institute of Technology Tign I al al an Dr. Pankaj Kumar-Porwa (Principal)

### If Statement

The if statement is used to check a condition: *if* the condition is true, we run a block of statements (called the *if-block*).

Syntax:

```
if test expression:
    statement(s)
```

Here, the program evaluates the test expression and will execute statement(s) only if the text expression is True.

If the text expression is False, the statement(s) is not executed.

Note:

- 1) In Python, the body of the if statement is indicated by the indentation. Body starts with an indentation and the first unindented line marks the end.
- 2) Python interprets non-zero values as True. None and 0 are interpreted as False.

#### **Python if Statement Flowchart**

Fig: Operation of if statement

For Techno India NJR Institute of Technology Canst Claated Dr. Pankaj Kumar-Porwa (Principal)
Example :

```
#Check if the number is positive, we print an appropriate message
num = 3
if num > 0:
    print(num, "is a positive number.")
print("this is always printed")
num = -1
if num > 0:
    print(num, "is a positive number.")
print("this is always printed")
```

When you run the program, the output will be:

3 is a positive number This is always printed This is also always printed.

In the above example, num > 0 is the test expression. The body of if is executed only if this evaluates to True.

When variable num is equal to 3, test expression is true and body inside body of if is executed.

If variable num is equal to -1, test expression is false and body inside body of if is skipped.

The print() statement falls outside of the if block (unindented). Hence, it is executed regardless of the test expression.

Python if...else Statement

Syntax of if...else

```
if test expression:
    Body of if
else:
    Body of else
```

The if..else statement evaluates test expression and will execute body of if only when test condition is True.

If the condition is False, body of else is executed. Indentation is used to separate the blocks.

For Techno India NJR Institute of Technology Tighon Time of recommony Tighon Time of recommony Dr. Pankaj Kumar-Borwa (Principal)

#### Python if..else Flowchart

Fig: Operation of if...else statement

#### Example of if...else

```
#A program to check if a person can vote
age = input("Enter Your Age")
if age >= 18:
        print("You are eligible to vote")
else:
        print("You are not eligible to vote")
```

In the above example, when if the age entered by the person is greater than or equal to 18, he/she can vote. Otherwise, the person is not eligible to vote

#### Python if...elif...else Statement

Syntax of if...elif...else

if test expression: Body of if elif test expression: Body of elif else: Body of else

The elif is short for else if. It allows us to check for multiple expressions.

If the condition for if is False, it checks the condition of the next elif block and so on.

If all the conditions are False, body of else is executed.

For Techno India NJR Institute of Technology Transf Transf Dr. Pankaj Kumar-Porwa (Principal)

Only one block among the several if...elif...else blocks is executed according to the condition.

The if block can have only one else block. But it can have multiple elif blocks.

#### Flowchart of if...elif...else

Fig: Operation of if...elif...else statement

#### Example of if...elif...else

#To check the grade of a student
Marks = 60
if marks > 75:
print("You get an A grade")
elif marks > 60:
 print("You get a B grade")
else:
 print("You get a C grade")

For Techno India NJR Institute of Technology Tan J Con Stand Dr. Pankaj Kumar-Borwa (Principal)

# Python Nested if statements

We can have an if...elif...else statement inside another if...elif...else statement. This is called nesting in computer programming.

Any number of these statements can be nested inside one another. Indentation is the only way to figure out the level of nesting. This can get confusing, so must be avoided if it can be.

#### Python Nested if Example

```
# In this program, we input a number
# check if the number is positive or
# negative or zero and display
# an appropriate message
# This time we use nested if
num = float(input("Enter a number: "))
if num >= 0:
    if num == 0:
        print("Zero")
    else:
        print("Positive number")
else:
    print("Negative number")
```

When you run the above program

#### Output 1

Enter a number: 5 Positive number

#### Output 2

Enter a number: -1 Negative number

#### **Output 3**

```
Enter a number: O
Zero
```

## Let's Practice

Let's Go through the If-Else Jupyter Notebook to get an experiential learning experience for If-Else. To download the Jupyter Notebook, go to the following link : <u>http://bit.ly/ifelse\_jupyter</u>

Note:

To open Jupyter notebook, go to start menu  $\rightarrow$  open anaconda prompt  $\rightarrow$  write "jupyter notebook"

For Techno India NJR Institute of Technology Const Clarkaj Kumar-Porwa (Principal)

# The For Loop

The for..in statement is another looping statement which *iterates* over a sequence of objects i.e. go through each item in a sequence. We will see more about sequences in detail in later chapters. What you need to know right now is that a sequence is just an ordered collection of items.

```
Syntax of for Loop
```

```
for val in sequence:
Body of for
```

Here, val is the variable that takes the value of the item inside the sequence on each iteration.

Loop continues until we reach the last item in the sequence. The body of for loop is separated from the rest of the code using indentation.

Flowchart of for Loop

```
Fig: operation of for loop
```

```
Example: Python for Loop
```

```
# Program to find the sum of all numbers stored in a list
# List of numbers
numbers = [6, 5, 3, 8, 4, 2, 5, 4, 11]
For Technology
Or. Pankaj Kumar/Porwa
(Principal)
```

```
# variable to store the sum
sum = 0
# iterate over the list
for val in numbers:
    sum = sum+val
# Output: The sum is 48
print("The sum is", sum)
```

when you run the program, the output will be:

The sum is 48

# The while Statement

The while statement allows you to repeatedly execute a block of statements as long as a condition is true. A while statement is an example of what is called a *looping* statement. A while statement can have an optional else clause.

Syntax of while Loop in Python

while test\_expression: Body of while

In while loop, test expression is checked first. The body of the loop is entered only if the test\_expression evaluates to True. After one iteration, the test expression is checked again. This process continues until the test\_expression evaluates to False. In Python, the body of the while loop is determined through indentation. Body starts with indentation and the first unindented line marks the end. Python interprets any non-zero valueas True. None and 0 are interpreted as False.

For Techno India NJR Institute of Technology Tight Institute of rectinicity) Tight Al 201 CM (Principal)

# Flowchart of while Loop

Fig: operation of while loop

# Example: Python while Loop

```
# Program to add natural
# numbers upto
# sum = 1+2+3+...+n
# To take input from the user,
# n = int(input("Enter n: "))
n = 10
# initialize sum and counter
sum = 0
i = 1
while i <= n:
    sum = sum + i
    i = i+1  # update counter
# print the sum
print("The sum is", sum)
```

When you run the program, the output will be:

Enter n: 10 The sum is 55

In the above program, the test expression will be True as long as our counter variable i is less than or equal to n (10 in our program).

For Techno India NJR Institute of Technology Tigh J CT 291 CV Dr. Pankaj KumarzBorwa (Principal)

We need to increase the value of the counter variable in the body of the loop. This is very important (and mostly forgotten). Failing to do so will result in an infinite loop (never ending loop).

Finally, the result is displayed.

# Let's Practice

Let's Go through the flow control Jupyter Notebook to get an experiential learning experience for 'for' and 'while' loop . To download the Jupyter Notebook, go to the following link : <u>http://bit.ly/loops\_jupyter</u>

Note:

To open Jupyter notebook, go to start menu  $\rightarrow$  open anaconda prompt  $\rightarrow$  write "jupyter notebook"

# Test Your Knowledge

Q1) Explain different types of 'If' statements with the help of a flowchart.

Q2) What is the difference between 'for' loop and 'while' loop. Explain with a help of a flowchart?

Q3) What are python nested if statements? Explain with example.

Q4) Write a program to find numbers which are divisible by 7 and multiple of 5 between 1200 and 2200.

Q5) Write a program to find the whether a number is prime or not using 'while' loop.

For Techno India NJR Institute of Technology Tigh J U Zal CA Dr. Pankaj KumargBorwa (Principal)

# Chapter 6 : Introduction to Packages

# Recap

Till now, you have worked around various python syntaxes. Conditional statements, Control flow statements, variables, datatypes, etc. are some of the concepts you now are quite familiar with. Let us test your skills and see how well have you understood it all.

# CHALLENGE TIME!

Here are 5 questions. Go through them individually and try answers them all.

1) Which of the following is NOT a legal variable name ?

mark_student	student_mark
StudentMark	_Mark_Student

2) What is the correct syntax to output the type of variable in python ?

print(typeof x)	print(typeof(x))
print(type(x))	print(type x)

3) What is the command to open Jupyter Notebook in anaconda prompt?

conda jupyter notebook	open jupyter notebook
jupyter notebook	activate jupyter notebook

4) Which of the following "if" statement will not be executed ?

if (a>b): print(a)	if (a>b): print(a)
if (a>b) :	if (a>b):
print(a)	print(a)

5) What will be the output of the following code?

x=2
while x<=10:
print(x)
x = x + 1
x = x + 1

For Techno India NJR Institute of Technology Unst Institute of Idditions Unst Ulzarov Dr. Pankaj Kumar8Porw (Principal)

Print number from 1 to 10	Print numbers from 1 to 9
Print numbers from 2 to 10	Print numbers from 2 to 9

Was the quiz easy?

Or did you find a need to take a look back at the concepts? Analyze your score and mention it here:

# Introduction

Let us assume we need to prepare the final result of your class. In your class, let's say there are 40 students. What should be the steps to prepare the result?

Let's see.

**Step 1:** Collect the exam scores for Mathematics, Science, Social Science, Hindi and English for all the students.

**Step 2:** Make a database (list) of students and their marks in each subject. It might look like this:

For Techno India NJR Institute of Technology Unst Institute of 1981 of 1981

Student's Roll No.	Marks in Science	Marks in Mathematics	Marks in Social Science	Marks in Hindi	Marks in English
Student 1	89	75	73	84	78
Student 2	54	65	57	75	48
 Student 40	 98	 100	 97	 94	 97

Step 3: New columns get added to the database for total marks and the percentage.

What is the formula to calculate percentage?

Student's Roll No.	Marks in	Marks in Mathematics	Marks in Social	Marks in	Marks in	Total Marks	Percentage
	Science		Science	Hindi	English		
Student 1	89	75	73	84	78	399	79.8%
Student 2	54	65	57	75	48	299	59.8%
Student 40	98	100	97	94	97	486	97.2%

**Step 4:** Finally, the database has been successfully created. Now, we need to analyze class performance as a whole. In this case, statistics come to our rescue. Various parameters that come into picture are mentioned below. Can you write how to find them all? List them down!

1. Average Score of the class.

2. Average percentage of the class performance.

3. Number of students passed / failed.

4. Success percentage of the class

For Techno India NJR Institute of Technology Gen I and Constitute of Technology Dr. Pankaj KumargBorwa (Principal)

5. Top 10 students of the class.

After going through this process, we can say that preparing the exam result manually is a tedious and time-consuming process. Therefore, it should be automated by creating apython script!

As you have already learnt a lot of Python concepts, list down the ones which can be used to create a python script of result creation.

There are a lot of functions which can be used in this process. But as it is all about numbers, we need to look for something that explicitly works around numbers so that the work becomes easier. With python, we get the advantage of using open-sourced packagesavailable on the internet. But what are packages? Let's find out.

For Techno India NJR Institute of Technology Dankaj Kumar84 (Principal)

# What is a package?

Here, we can draw analogy for packages with the book shelf. The history bookshelf is nothing but a package which contains multiple books of similar type and provides the user with a variety to choose from to make it easier for them to find out the exact information needed. In other words, a package is nothing but a space where you can find codes or functions or modules of similar type. There are various packages readily available to use for free (perks of python being an open-sourced language) for various purposes. Some of the readily available packages are:

#### NumPy

- A package created to work around numerical arrays in python.
- Handy when it comes to working with large numerical databases and calculations around it.

#### OpenCV

 An image processing package which can explicitly work around images and can be used for image manipulation and processing like cropping, resizing, editing, etc.

#### Matplotlib

- A package which helps in plotting the analytical (numerical) data in graphical form.
- It helps the user in visualizing the data thereby helping them in understanding it better.

#### NLTK

- NLTK stands for Natural Language Tool Kit and it helps in tasks related to textual data.
- It is one of the most commonly used package for Natural Language Processing.

#### Pandas

- A package which helps in handling 2-dimensional data tables in python.
- It is useful when we need to work with data from excel sheets and other databases.

For Techno India NJR Institute of Technology पैकर्ज परिवाल Dr. Pankaj Kumargerw

## Package Installation

Using these packages is easy. All we need to do is install the package and import it wherever required.

Any package can be installed by directly writing the following command in the Anaconda

# conda install numpy

The name of package can be replaced at the end of the statement.

Multiple packages can also be installed in just one command:

# conda install numpy pandas matplotlib

This would install NumPy, Pandas and Matplotlib altogether.

Once you begin the installation, after a bit of processing, the prompt would ask if you wish to proceed for the installation or not:

# Proceed ([y]/n)?

Press **Y** to continue with the installation. Within a few minutes, the packages will be installed and would be ready to use.

## Working with a package

To use a package, we need to import it in the script wherever it is required. There are various versions of importing a package in Python:

# import numpy

**Meaning:** Import numpy in the file to use its functionalities in the file to which it has been imported.

# import numpy as np

Meaning: Import numpy and refer to it as np wherever it is used.

# from numpy import array

**Meaning:** import only one functionality (array) from the whole numpy package. While this gives faster processing, it limits the package's usability.

# from numpy import array as arr

**Meaning:** Import only one functionality (array) from the whole numpy package and refer to it as arr wherever it is used.

A lot of other combinations can also be explored while importing packages like importing multiple functionalities of a package in a single statement, etc.

For Techno India NJR Institute of Technology Pankaj Kumar

## What is NumPy?

NumPy, which stands for Numerical Python, is the fundamental package for mathematical and logical operations on arrays in Python. It is a commonly used package when it comes to working around numbers. NumPy gives a wide range of arithmetic operations around numbers giving us an easier approach in working with them. NumPy also works with arrays, which is nothing but homogenous collection of Data.

An array is nothing but a set of multiple values which are of same datatype. They can be numbers, characters, Booleans, etc. but only one datatype can be accessed through an array. In NumPy, the arrays used are known as ND-arrays (N-Dimensional Arrays) as NumPy comes with a feature of creating n-dimensional arrays in python.

An array can easily be compared to a list. Let us take a look how different they are:

	NumPy Arrays		Lists
1.	Homogenous collection of Data.	1.	Heterogenous collection of Data.
2.	Can contain only one type of data, hence not flexible with datatypes.	2.	Can contain multiple types of data, hence flexible with datatypes.
3.	Cannot be directly initialized. Can be operated with Numpy package only.	3.	Can be directly initialized as it is the part of python syntax.
4.	Direct numerical operations can be done. For example, dividing the whole array by 3 divides every element by 3.	4.	Direct numerical operations are not possible. For example, dividing the whole list by 3 cannot divide every element by
5.	Widely used for arithmetic operations.		3.
6.	Arrays take less memory space.	5.	Widely used for data management.
7.	Example: To create a Numpy array 'A':	6. 7.	Lists acquire more memory space. Example: To create a list:
im	iport numpy		
A=	numpy.array([1,2,3,4,5,6,7,8,9,0])		
		A	= [1,2,3,4,5,6,7,8,9,0]

Since NumPy package is not included in the basic Python installation, we need to install it separately. Once it is installed, it can be readily used in any Python code whenever imported.

For Techno India NJR Institute of Technology Tan T Tal Col Dr. Pankaj KumargPorwa (Principal)

# Exploring NumPy!

NumPy package provides us with various features and functions which helps us in arithmetic and logical operations. Let us look at some of them:

1. **NumPy Arrays:** As discussed before, arrays are homogenous collection of datatypes. With NumPy, we can create n-dimensional arrays (where n can be any integer) and operate on them using other mathematical functions.

Here are some ways by which you can create arrays using NumPy package assuming the NumPy packages is imported already.

Function	Code
Creating a Numpy Array	numpy.array([1,2,3,4,5])
Creating a 2-Dimensional zero array (4X3 – 4 rows and 3 columns)	<pre>numpy.zeros((4,3))</pre>
Creating an array with 5 random values	<pre>numpy.random.random(5)</pre>
Creating a 2-Dimensional constant value array (3X4 – 3 rows and 4 columns) having all 6s	<pre>numpy.full((3,4),6)</pre>
Creating a sequential array from 0 to 30 with gaps of 5	<pre>numpy.arrange(0,30,5)</pre>

One of the features of array is that we can perform arithmetic functions on the elements of the array directly by performing them on the whole array.

Let us assume the array is "ARR" and it has been initialized as: ARR = numpy.array([1,2,3,4,5])

Now, let us look at various operations that could be implemented on this array:

Function	Code
Adding 5 to each element	ARR + 5
Divide each element by 5	ARR / 5
Squaring each element	ARR ** 2
Accessing 2 <sup>nd</sup> element of the array (element count starts from 0)	ARR[1]
Multiplying 2 arrays {consider BRR = numpy.array([6,7,8,9,0]) }	ARR * BRR

As you can see, direct arithmetical operations can be implemented on individual array elements just by manipulating the whole array variable.

For Techno India NJR Institute of Technology Tan J and Ang Dr. Pankaj KumargBorwa (Principal)

Let us look at the functions which talk about the properties of an array:

Function	Code
Type of an array	type(ARR)
Check the dimensions of an array	ARR.ndim
Shape of an array	ARR.shape
Size of an array	ARR.size
Datatype of elements stored in the array	ARR.dtype

Some other mathematical functions available with NumPy are:

Function	Code
Finding out maximum element of an array	ARR.max()
Finding out row-wise maximum elements	ARR.max(axis = 1)
Finding out column-wise minimum elements	ARR.min(axis = 0)
Sum of all array elements	ARR.sum()

# Let's Practice!

#### TASK 1

To understand these functions better, let us try and execute all the functions we read above on a Jupyter Notebook. To download the Jupyter Notebook, go to the following link: <u>http://bit.ly/numpy\_jupyter</u> and download NumPy Basic notebook.

#### TASK 2

Go through the NumPy Jupyter Notebook to get an experiential learning experience for NumPy. To download the Jupyter Notebook, go to the following link : <u>http://bit.ly/numpy\_jupyter</u> and download NumPy Advance notebook

#### Note:

To open Jupyter notebook, go to start menu  $\rightarrow$  open anaconda prompt  $\rightarrow$  write "jupyter notebook"

# Test Your Knowledge

Q1) What is a package ? Give Example with its use.

- Q2) What is the command to install a package.
- Q3) How can we use a package in a code? Explain with an example.
- Q4) What is a NumPy array ? Give example
- Q5) What is a difference between a NumPy array and python list.
